

THE WEAKLY NONLINEAR MAGNETOROTATIONAL INSTABILITY IN A WIDE-GAP CHANNEL FLOW

CLARK, S.E.¹ AND OISHI, J.S.^{2,3}

Draft version June 9, 2016

ABSTRACT

Wide gap formulation and preliminary results

1. INTRODUCTION

2. WIDE GAP EQUATIONS

Many investigations of the MRI use the “thin gap” approximation, in which the radial extent of the fluid channel is taken to be much smaller than the radius of curvature. That is, for a channel center r_0 bounded by inner and outer radii r_1 and r_2 , respectively, the thin gap approximation applies when $r_0 \gg (r_2 - r_1)$. The thin gap approximation simplifies the MRI equations by excluding curvature terms, because the flow through a thin gap can be taken to be approximately linear in ϕ , i.e. Cartesian. In this work we undertake the first (to our knowledge) weakly nonlinear analysis of the MRI in the wide gap regime, where the channel width may be comparable to or larger than its distance from the center of rotation.

The basic equations solved are the momentum and induction equations,

$$\partial_t \mathbf{u} + \mathbf{u} \cdot \nabla \mathbf{u} = -\frac{1}{\rho} \nabla P - \nabla \Phi + \frac{1}{\rho} (\mathbf{J} \times \mathbf{B}) + \nu \nabla^2 \mathbf{u} \quad (1)$$

and

$$\partial_t \mathbf{B} = \nabla \times (\mathbf{u} \times \mathbf{B}) + \eta \nabla^2 \mathbf{B}, \quad (2)$$

where P is the gas pressure, ν is the kinematic viscosity, η is the microscopic diffusivity, $\nabla \Phi$ is the gravitational force per unit mass, and the current density is $\mathbf{J} = \nabla \times \mathbf{B}$. We solve these equations subject to the incompressible fluid and solenoidal magnetic field constraints,

$$\nabla \cdot \mathbf{u} = 0 \quad (3)$$

and

$$\nabla \cdot \mathbf{B} = 0. \quad (4)$$

We perturb these equations axisymmetrically in a cylindrical (r, ϕ, z) geometry, i.e. $\mathbf{u} = \mathbf{u}_0 + \mathbf{u}_1$ and $\mathbf{B} = \mathbf{B}_0 + \mathbf{B}_1$, where \mathbf{u}_0 and \mathbf{B}_0 are defined below. We define a Stokes stream function Ψ such that

$$\mathbf{u}_1 = \begin{bmatrix} \frac{1}{r} \partial_z \Psi \hat{\mathbf{r}} \\ u_\phi \hat{\phi} \\ -\frac{1}{r} \partial_r \Psi \hat{\mathbf{z}} \end{bmatrix}, \quad (5)$$

and define the magnetic vector potential A analogously. These definitions automatically satisfy Equations 3 and 4 for axisymmetric disturbances.

The astrophysical magnetorotational instability operates in accretion disks and in stellar interiors, environments where fluid rotation is strongly regulated by gravity. In accretion disks, differential rotation is imposed gravitationally by a central body, so the rotation profile is forced to be Keplerian. Clearly a gravitationally enforced Keplerian flow is inaccessible to laboratory study, so differential rotation is created by rotating an inner cylinder faster than an outer cylinder (a Taylor-Couette setup). For a nonideal fluid subject to no-slip boundary conditions, the base flow is

$$\Omega(r) = a + \frac{b}{r^2}, \quad (6)$$

where $a = (\Omega_2 r_2^2 - \Omega_1 r_1^2)/(r_2^2 - r_1^2)$, $b = r_1^2 r_2^2 (\Omega_1 - \Omega_2)/(r_2^2 - r_1^2)$, and Ω_1 and Ω_2 are the rotation rates at the inner and outer cylinder radii, respectively. In the laboratory, r_1 and r_2 are typically fixed by experimental design. However

¹ Department of Astronomy, Columbia University, New York, NY

² Department of Astrophysics, American Museum of Natural History, New York, NY

³ Department of Physics, SUNY Farmingdale

Ω_1 and Ω_2 may be chosen such that the flow in the center of the channel is approximately Keplerian. Defining a shear parameter q , we see that for Couette flow,

$$q(r) \equiv -\frac{d \ln \Omega}{d \ln r} = \frac{2b}{ar^2 + b}. \quad (7)$$

Thus through judicious choice of cylinder rotation rates, we can set $q(r_0) = 3/2$, for quasi-Keplerian flow. Note that in the thin gap approximation we have the freedom to choose any rotation profile, as the narrow gap width imposes a linear shear (constant q). Our base velocity is $\mathbf{u}_0 = r\Omega(r)\hat{\phi}$. We initialize an axial magnetic field $\mathbf{B}_0 = B_0\hat{z}$.

Our perturbed system is

$$\begin{aligned} \frac{1}{r}\partial_t(\nabla^2\Psi - \frac{2}{r}\partial_r\Psi) - \frac{2}{\beta}\frac{1}{r}B_0\partial_z(\nabla^2A - \frac{2}{r}\partial_rA) - \frac{2}{r}u_0\partial_zu_\phi - \frac{1}{\text{Re}}\left[\nabla^2(\frac{1}{r}\nabla^2\Psi) - \frac{1}{r^3}\partial_r^2\Psi - \frac{1}{r^4}\partial_r\Psi\right] \\ = -J(\Psi, \frac{1}{r^2}(\nabla^2\Psi - \frac{2}{r}\partial_r\Psi)) + \frac{2}{\beta}J(A, \frac{1}{r^2}(\nabla^2A - \frac{2}{r}\partial_rA)) - \frac{2}{\beta}\frac{2}{r}B_\phi\partial_zB_\phi + \frac{2}{r}u_\phi\partial_zu_\phi \end{aligned} \quad (8)$$

$$\partial_tu_\phi + \frac{1}{r^2}u_0\partial_z\Psi + \frac{1}{r}\partial_ru_0\partial_z\Psi - \frac{2}{\beta}B_0\partial_zB_\phi - \frac{1}{\text{Re}}(\nabla^2u_\phi - \frac{1}{r^2}u_\phi) = \frac{2}{\beta}\frac{1}{r}J(A, B_\phi) - \frac{1}{r}J(\Psi, u_\phi) + \frac{2}{\beta}\frac{1}{r^2}B_\phi\partial_zA - \frac{1}{r^2}u_\phi\partial_z\Psi \quad (9)$$

$$\partial_tA - B_0\partial_z\Psi - \frac{1}{\text{Rm}}(\nabla^2A - \frac{2}{r}\partial_rA) = \frac{1}{r}J(A, \psi) \quad (10)$$

$$\partial_tB_\phi + \frac{1}{r^2}u_0\partial_zA - B_0\partial_zu_\phi - \frac{1}{r}\partial_ru_0\partial_zA - \frac{1}{\text{Rm}}(\nabla^2B_\phi - \frac{1}{r^2}B_\phi) = \frac{1}{r}J(A, u_\phi) + \frac{1}{r}J(B_\phi, \psi) + \frac{1}{r^2}B_\phi\partial_z\psi - \frac{1}{r^2}u_\phi\partial_zA \quad (11)$$

where J is the Jacobian $J(x, y) \equiv \partial_zx\partial_ry - \partial_rx\partial_zy$. Note that in the above, $\nabla^2x \equiv \partial_r^2x + \partial_z^2x + \frac{1}{r}\partial_rx$. Equations 8 - 11 are nondimensionalized, where lengths have been scaled by r_0 , velocities by $r_0\Omega_0$, densities by ρ_0 , and magnetic fields by B_0 ; where B_0 appears in the above it is formally unity. $\Omega_0 = \Omega(r_0)$ is the rotation rate at the center of the channel. We introduce the Reynolds number $\text{Re} = \Omega_0 r_0^2/\nu$, the magnetic Reynolds number $\text{Rm} = \Omega_0 r_0^2/\eta$, and a plasma beta parameter $\beta = \Omega_0^2 r_0^2 \rho_0/B_0^2$. If we define the dimensional cylindrical coordinate $r = r_0(1 + \delta x)$, the thin gap equations are recovered in the limit $\delta \rightarrow 0$.

We solve the system subject to periodic vertical boundary conditions and no-slip, perfectly conducting radial boundary conditions.

3. WEAKLY NONLINEAR PERTURBATION ANALYSIS

Just as in the weakly nonlinear analyses of [Umurhan et al. 2007b](#) and [Clark & Oishi 2016a](#), we tune the system away from marginality by taking $B_0 \rightarrow B_0(1 - \epsilon^2)$, where $\epsilon \ll 1$. We parameterize scale separation as $Z = \epsilon z$ and $T = \epsilon^2 t$, where Z and T are slowly varying spatial and temporal scales, respectively. We group the fluid variables into a state vector $\mathbf{V} = [\Psi, u, A, B]^T$, such that the full nonlinear system can be expressed as

$$\mathcal{D}\partial_t\mathbf{V} + \mathcal{L}\mathbf{V} + \epsilon^2\tilde{\mathcal{G}}\mathbf{V} + \mathbf{N} = 0, \quad (12)$$

where \mathcal{D} , \mathcal{L} , and $\tilde{\mathcal{G}}$ are matrices defined in Appendix A, and \mathbf{N} is a vector containing all nonlinear terms. We then expand the variables in a perturbation series $\mathbf{V} = \epsilon\mathbf{V}_1 + \epsilon^2\mathbf{V}_2 + \epsilon^3\mathbf{V}_3 + h.o.t.$. The perturbed system can then be expressed at each order by the equations

$$\mathcal{O}(\epsilon) : \mathcal{L}\mathbf{V}_1 + \mathcal{D}\partial_t\mathbf{V}_1 = 0 \quad (13)$$

$$\mathcal{O}(\epsilon^2) : \mathcal{L}\mathbf{V}_2 + \tilde{\mathcal{L}}_1\partial_Z\mathbf{V}_1 + \mathbf{N}_2 = 0 \quad (14)$$

$$\mathcal{O}(\epsilon^3) : \mathcal{L}\mathbf{V}_3 + \mathcal{D}\partial_T\mathbf{V}_1 + \tilde{\mathcal{L}}_1\partial_Z\mathbf{V}_2 + \tilde{\mathcal{L}}_2\partial_Z^2\mathbf{V}_1 + \tilde{\mathcal{G}}\mathbf{V}_1 + \mathbf{N}_3. \quad (15)$$

See Appendix A for the definition of matrices and nonlinear vectors, and a thorough derivation. We emphasize that Equations 13 - 15 have the same form as these equations in the thin gap case, although the matrices (which contain all radial derivatives) are significantly different in this wide gap formulation. This is because we do not have slow variation in the radial dimension. The slow variation in Z and T are parameterized as an amplitude function $\alpha(Z, T)$ which modulates the flow in these dimensions. This parameterization coupled with the boundary conditions lead us to an ansatz linear solution $\mathbf{V}_1 = \alpha(Z, T)\mathbb{V}_{11}(r)e^{ik_z z} + c.c.$, where the radial variation is contained in \mathbb{V}_{11} . We defer full expressions and derivations thereof to the Appendix, and focus here on features of the wide gap system which distinguish it from the thin gap limit.

First, the result of the weakly nonlinear analysis is a single amplitude equation for α . We find

$$\partial_T \alpha = b\alpha + d\nabla^2 \alpha - c\alpha |\alpha^2|, \quad (16)$$

a Ginzburg-Landau equation (e.g. Aranson & Kramer (2002)). Here we note a departure from the behavior of the thin-gap system. The purely conducting boundary condition states that the axial component of the current ($\mathbf{J}_z = [\nabla \times \mathbf{B}]_z$) must be zero at the walls. In the thin gap geometry, the purely conducting boundary condition on the azimuthal magnetic field is $\partial_x(B_y) = 0$ for axisymmetric perturbations. A spatially constant azimuthal field satisfies both the thin-gap MRI equations and this boundary condition. This neutral mode is formally included in the analysis of Umurhan et al. 2007b and yields a second amplitude equation in the form of a simple diffusion equation. This amplitude equation decouples from the GLE because of the translational symmetry of the thin-gap geometry. Because that symmetry is not preserved in the wide-gap case, Umurhan et al. postulate that slow variation in the wide-gap geometry will be governed by two coupled amplitude equations. However, the wide-gap conducting boundary condition $J_z = \frac{1}{r} \partial_r(rB_\phi) = 0$, together with the purely geometric term in Equation 11, conspire to prevent the wide-gap geometry from sustaining a neutral mode. We note that a neutral mode of the form $B_\phi(r) \propto \frac{1}{r}$ would exist in a resistance-free approximation.

The preservation of symmetries in the thin-gap geometry is worth a closer look, as its absence in the wide gap case is the source of many differences in the systems. Latter et al. 2015 point out that in the ideal limit ($\nu, \eta \rightarrow 0$), the linearized system described by the lefthand side of Equations 8 - 11 can be expressed as a Shrödinger equation for the radial velocity. Similarly combining equations to obtain a single expression for Ψ , we find that the thin-gap limit linear ideal MRI can be expressed as

$$\partial_x^2 \Psi + k_z^2 U(x) \Psi = 0 \quad (17)$$

where $U(x) = 3/v_A^2 k_z^2 + 1$ at marginality. When no-slip radial boundary conditions are applied, the thin-gap MRI system resembles a particle in a box with a radially constant potential well. Thus thin-gap linear MRI modes must be eigenstates of parity. These symmetries are preserved in the nonlinear MRI terms because they are nonlinear combinations of lower-order eigenfunctions. In the wide gap case, the “potential” $U(r)$ is a function of r , so symmetric and antisymmetric modes are no longer required.

The nonlinear terms, detailed in Appendix B, represent an interesting departure from the thin-gap theory. The thin-gap nonlinear terms at both second and third orders are linear combinations of Jacobians. The nonlinear terms in the wide-gap case differ from their thin-gap analogues with in the addition of vertical advective terms. These terms derive from the advective derivatives in the momentum and induction equations, but are filtered out in the thin-gap approximation. These advective terms allow the nonlinear contributions at both second and third order (i.e. N_2 and N_3) not to individually satisfy the boundary conditions on Ψ and u . (I’m just guessing but this may lead to higher torque on inner cylinder – should calculate)

4. CHANNEL MODES

Channel modes are radially independent linear MRI modes which are, under certain conditions, exact nonlinear solutions to the MRI equations.

APPENDIX

A. DETAILED EQUATIONS

B. NONLINEAR TERMS

Here we detail the perturbative expansion of the nonlinear vector \mathbf{N} in Equation 12.

$$\mathbf{N} = \epsilon^2 \mathbf{N}_2 + \epsilon^3 \mathbf{N}_3 \quad (\text{B1})$$

$$N_2^\Psi = J(\Psi_1, \frac{1}{r^2} \nabla^2 \Psi_1) + J(\Psi_1, -\frac{2}{r^3} \partial_r \Psi_1) - \frac{2}{\beta} J(A_1, \frac{1}{r^2} \nabla^2 A_1) - \frac{2}{\beta} J(A_1, -\frac{2}{r^3} \partial_r A_1) - \frac{2}{r} u_1 \partial_z u_1 + \frac{2}{\beta} \frac{2}{r} B_1 \partial_z B_1 \quad (\text{B2})$$

$$N_2^u = \frac{1}{r} J(\Psi_1, u_1) - \frac{1}{r} \frac{2}{\beta} J(A_1, B_1) + \frac{1}{r^2} u_1 \partial_z \Psi_1 - \frac{2}{\beta} \frac{1}{r^2} B_1 \partial_z A_1 \quad (\text{B3})$$

$$N_2^A = -\frac{1}{r} J(A_1, \Psi_1) \quad (\text{B4})$$

$$N_2^B = -\frac{1}{r} J(A_1, u_1) - \frac{1}{r} J(B_1, \Psi_1) - \frac{1}{r^2} B_1 \partial_z \Psi_1 + \frac{1}{r^2} u_1 \partial_z A_1 \quad (\text{B5})$$

$$\begin{aligned} N_3^\Psi = & J(\Psi_1, \frac{1}{r^2} \nabla^2 \Psi_2) + J(\Psi_2, \frac{1}{r^2} \nabla^2 \Psi_1) + 2J(\Psi_1, \frac{1}{r^2} \partial_z \partial_z \Psi_1) + J(\Psi_1, -\frac{2}{r^3} \partial_r \Psi_2) + J(\Psi_2, -\frac{2}{r^3} \partial_r \Psi_1) \\ & + \tilde{J}(\Psi_1, \frac{1}{r^2} \nabla^2 \Psi_1) + \tilde{J}(\Psi_1, -\frac{2}{r^3} \partial_r \Psi_1) - \frac{2}{\beta} J(A_1, \frac{1}{r^2} \nabla^2 A_2) - \frac{2}{\beta} J(A_2, \frac{1}{r^2} \nabla^2 A_1) - \frac{4}{\beta} J(A_1, \frac{1}{r^2} \partial_z \partial_z A_1) \\ & - \frac{2}{\beta} J(A_1, -\frac{2}{r^3} \partial_r A_2) - \frac{2}{\beta} J(A_2, -\frac{2}{r^3} \partial_r A_1) - \frac{2}{\beta} \tilde{J}(A_1, \frac{1}{r^2} \nabla^2 A_1) - \frac{2}{\beta} \tilde{J}(A_1, -\frac{2}{r^3} \partial_r A_1) \\ & - \frac{2}{r} u_1 \partial_z u_2 - \frac{2}{r} u_2 \partial_z u_1 - \frac{2}{r} u_1 \partial_z u_1 + \frac{2}{\beta} \frac{2}{r} B_1 \partial_z B_2 + \frac{2}{\beta} \frac{2}{r} B_2 \partial_z B_1 + \frac{2}{\beta} \frac{2}{r} B_1 \partial_z B_1 \end{aligned} \quad (\text{B6})$$

$$\begin{aligned} N_3^u = & \frac{1}{r} J(\Psi_1, u_2) + \frac{1}{r} J(\Psi_2, u_1) + \frac{1}{r} \tilde{J}(\Psi_1, u_1) - \frac{1}{r} \frac{2}{\beta} J(A_1, B_2) - \frac{1}{r} \frac{2}{\beta} J(A_2, B_1) - \frac{1}{r} \frac{2}{\beta} \tilde{J}(A_1, B_1) \\ & + \frac{1}{r^2} u_1 \partial_z \Psi_2 + \frac{1}{r^2} u_2 \partial_z \Psi_1 + \frac{1}{r^2} u_1 \partial_z \Psi_1 - \frac{2}{\beta} \frac{1}{r^2} B_1 \partial_z A_2 - \frac{2}{\beta} \frac{1}{r^2} B_2 \partial_z A_1 - \frac{2}{\beta} \frac{1}{r^2} B_1 \partial_z A_1 \end{aligned} \quad (\text{B7})$$

$$N_3^A = -\frac{1}{r} J(A_1, \Psi_2) - \frac{1}{r} J(A_2, \Psi_1) - \frac{1}{r} \tilde{J}(A_1, \Psi_1) \quad (\text{B8})$$

$$\begin{aligned} N_3^B = & -\frac{1}{r} J(A_1, u_2) - \frac{1}{r} J(A_2, u_1) - \frac{1}{r} \tilde{J}(A_1, u_1) - \frac{1}{r} J(B_1, \Psi_2) - \frac{1}{r} J(B_2, \Psi_1) - \frac{1}{r} \tilde{J}(B_1, u_1) \\ & - \frac{1}{r^2} B_1 \partial_z \Psi_2 - \frac{1}{r^2} B_2 \partial_z \Psi_1 - \frac{1}{r^2} B_1 \partial_z \Psi_1 + \frac{1}{r^2} u_1 \partial_z A_2 + \frac{1}{r^2} u_2 \partial_z A_1 + \frac{1}{r^2} u_1 \partial_z A_1 \end{aligned} \quad (\text{B9})$$
